Clinic Supply & Expiration Tracker

Multi-clinic supply control with lot tracking, counts, and retry-safe receiving

The problem

Community clinics often track medical supplies on paper or in spreadsheets. Three problems follow: expiring stock is used after newer stock, physical counts that differ from records are corrected without a trail, and a receipt resubmitted after a dropped connection is counted twice.

What it does

- **Inventory** by clinic and storage area, with expiration status.
- **Receiving** in multi-line receipts. Purchase units, such as cases, convert to base units on the server.
- **Issuing** against a chosen lot.
- **Counts** that flag discrepancies beyond a set tolerance, then complete or cancel.
- **History** of every stock movement, with the actor, reason, and time.
- **Retry safety.** Each write carries a submission key, so a repeated request returns the saved result instead of posting again.

Verified

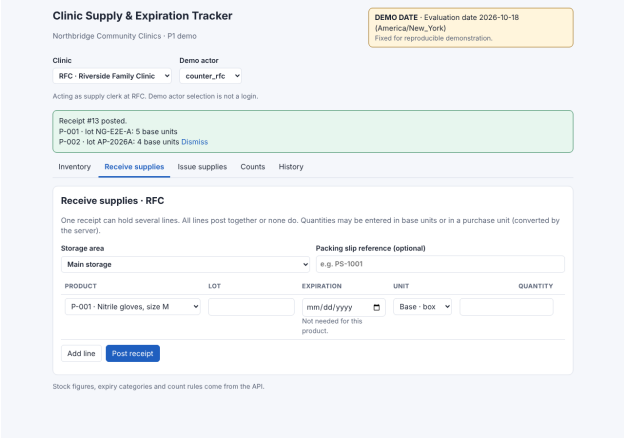

Automated tests cover the database rules and the API. Browser checks cover the walkthrough, failure recovery, and keyboard use, and an automated accessibility audit runs across light, dark, and phone layouts.
Screen-reader checks were carried out manually in Chrome and Safari, with 200% zoom and a physical phone also checked. Results, including limitations, are recorded in the repository.

In the application

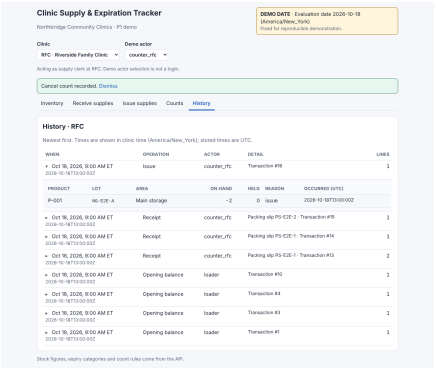

Receiving: a posted receipt

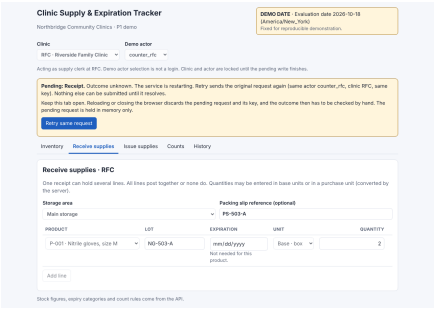

Issuing: a posted issue

Count with a discrepancy

History with movements

Pending write after a dropped request

All names, clinics, products, and quantities are fictional. The demonstration uses a fixed date and a demo packaging assumption (one case equals twelve boxes); it is not a supplier specification.
